

▼ Thasina Tabashum

In this tutorial, you will learn how to classify images of cats and dogs by using transfer learning from a pre-trained model. A pre-trained model is a saved network that was previously trained on a large dataset, typically on a large dataset like ImageNet. You can either use the pretrained model as is or use transfer learning to customize this model to a given task. The intuition behind transfer learning for image classification is that if a model is trained on a large dataset, it can effectively serve as a generic model of the visual world. You can then take advantage of these learned features by fine-tuning the model for your specific task, rather than training from scratch by training a large model on a large dataset.

In this notebook, you will try two ways to customize a pretrained model:

1. Feature Extraction: Use the representations learned by a previous network to extract meaningful features. Then, add a new classifier, which will be trained from scratch, on top of the pretrained model so that it can classify the new dataset. This method is useful when you have a small dataset and want to leverage the knowledge learned previously for the dataset.

You do not need to (re)train the entire model. The base convolutional network already contains layers for classifying pictures. However, the final, classification part of the pretrained model is specific to the classes it was trained on. You can then fine-tune the model to be specific to the set of classes on which the model was trained.

2. Fine-Tuning: Unfreeze a few of the top layers of a frozen model base and jointly train both the new layers and the unfrozen layers of the base model. This allows us to "fine-tune" the higher-order feature representations to be more relevant for the specific task.

You will follow the general machine learning workflow.

1. Examine and understand the data
2. Build an input pipeline, in this case using Keras ImageDataGenerator
3. Compose the model
 - Load in the pretrained base model (and pretrained weights)
 - Stack the classification layers on top
4. Train the model
5. Evaluate model

```
import os
```

```
import numpy as np
```

```
import matplotlib.pyplot as plt
```

```
import tensorflow as tf
```

▼ Data preprocessing

▼ Data download

Use [TensorFlow Datasets](#) to load the cats and dogs dataset.

This `tfds` package is the easiest way to load pre-defined data. If you have your own data, and are interested in TensorFlow see [loading image data](#)

```
import tensorflow_datasets as tfds
tfds.disable_progress_bar()
```

The `tfds.load` method downloads and caches the data, and returns a `tf.data.Dataset` object. There are also methods for manipulating data and piping it into your model.

Since "cats_vs_dogs" doesn't define standard splits, use the `subsplit` feature to divide it into (train, validation, test) splits respectively.

```
(raw_train, raw_validation, raw_test), metadata = tfds.load(
    'cats_vs_dogs',
    split=['train[:80%]', 'train[80%:90%]', 'train[90%:]'],
    with_info=True,
    as_supervised=True,
)
```

The resulting `tf.data.Dataset` objects contain (image, label) pairs where the images have variable size and the labels are integer scalar.

```
print(raw_train)
print(raw_validation)
print(raw_test)
```

```
<DatasetV1Adapter shapes: ((None, None, 3), ()), types: (tf.uint8, tf.int64)>
<DatasetV1Adapter shapes: ((None, None, 3), ()), types: (tf.uint8, tf.int64)>
<DatasetV1Adapter shapes: ((None, None, 3), ()), types: (tf.uint8, tf.int64)>
```

Show the first two images and labels from the training set:

```
get_label_name = metadata.features['label'].int2str

for image, label in raw_train.take(2):
    plt.figure()
```

```
plt.imshow(image)
plt.title(get_label_name(label))
```

▼ Format the Data

Use the `tf.image` module to format the images for the task.

Resize the images to a fixed input size, and rescale the input channels to a range of `[-1,1]`

```
IMG_SIZE = 160 # All images will be resized to 160x160
```

```
def format_example(image, label):
    image = tf.cast(image, tf.float32)
    image = (image/127.5) - 1
    image = tf.image.resize(image, (IMG_SIZE, IMG_SIZE))
    return image, label
```

Apply this function to each item in the dataset using the map method:

```
train = raw_train.map(format_example)
validation = raw_validation.map(format_example)
```

```
validation = raw_validation.map(format_example)
test = raw_test.map(format_example)
```

Now shuffle and batch the data.

```
BATCH_SIZE = 32
SHUFFLE_BUFFER_SIZE = 1000
```

```
train_batches = train.shuffle(SHUFFLE_BUFFER_SIZE).batch(BATCH_SIZE)
validation_batches = validation.batch(BATCH_SIZE)
test_batches = test.batch(BATCH_SIZE)
```

Inspect a batch of data:

```
for image_batch, label_batch in train_batches.take(1):
    pass
```

```
image_batch.shape
```

```
TensorShape([32, 160, 160, 3])
```

▼ Create the base model from the pre-trained convnets

You will create the base model from the **MobileNet V2** model developed at Google. This is pre-trained consisting of 1.4M images and 1000 classes. ImageNet is a research training dataset with a wide variety of objects. This base of knowledge will help us classify cats and dogs from our specific dataset.

First, you need to pick which layer of MobileNet V2 you will use for feature extraction. The very last layer (the layer that outputs the final classification probabilities) is not very useful. Instead, you will look for the layer just before the final layer. This layer is called the "bottleneck layer". The bottleneck layer is compared to the final/top layer.

First, instantiate a MobileNet V2 model pre-loaded with weights trained on ImageNet. By specifying the input_shape parameter, you can create a network that doesn't include the classification layers at the top, which is ideal for feature extraction.

```
IMG_SHAPE = (IMG_SIZE, IMG_SIZE, 3)

# Create the base model from the pre-trained model MobileNet V2
base_model = tf.keras.applications.MobileNetV2(input_shape=IMG_SHAPE,
                                                include_top=False,
                                                weights='imagenet')
```

This feature extractor converts each 160x160x3 image into a 5x5x1280 block of features. See what it

```
feature_batch = base_model(image_batch)
```

```
print(feature_batch.shape)
```

 (32, 5, 5, 1280)

▼ Feature extraction

In this step, you will freeze the convolutional base created from the previous step and to use as a feature classifier on top of it and train the top-level classifier.

▼ Freeze the convolutional base

It is important to freeze the convolutional base before you compile and train the model. Freezing (by weights in a given layer from being updated during training. MobileNet V2 has many layers, so setting will freeze all the layers.

```
base_model.trainable = False
```

```
# Let's take a look at the base model architecture  
base_model.summary()
```

Model: "mobilenetv2_1.00_160"

▼ Add a classification head

To generate predictions from the block of features, average over the spatial 5x5 spatial locations, use `tf.keras.layers.GlobalAveragePooling2D` layer to convert the features to a single 1280-element vector.

```
global_average_layer = tf.keras.layers.GlobalAveragePooling2D()
feature_batch_average = global_average_layer(feature_batch)
print(feature_batch_average.shape)
```

 (32, 1280)

Apply a `tf.keras.layers.Dense` layer to convert these features into a single prediction per image. You can use `softmax` because this prediction will be treated as a `logit`, or a raw prediction value. Positive numbers predic

0.

```
prediction_layer = tf.keras.layers.Dense(1)
prediction_batch = prediction_layer(feature_batch_average)
print(prediction_batch.shape)
```

 (32, 1)

Now stack the feature extractor, and these two layers using a `tf.keras.Sequential` model:

```
model = tf.keras.Sequential([
    base_model,
    global_average_layer,
    prediction_layer
])
```

▼ Compile the model

You must compile the model before training it. Since there are two classes, use a binary cross-entropy model provides a linear output.

```
base_learning_rate = 0.0001
model.compile(optimizer=tf.keras.optimizers.RMSprop(lr=base_learning_rate),
              loss=tf.keras.losses.BinaryCrossentropy(from_logits=True),
              metrics=['accuracy'])
```

```
model.summary()
```

▼ Learning curves

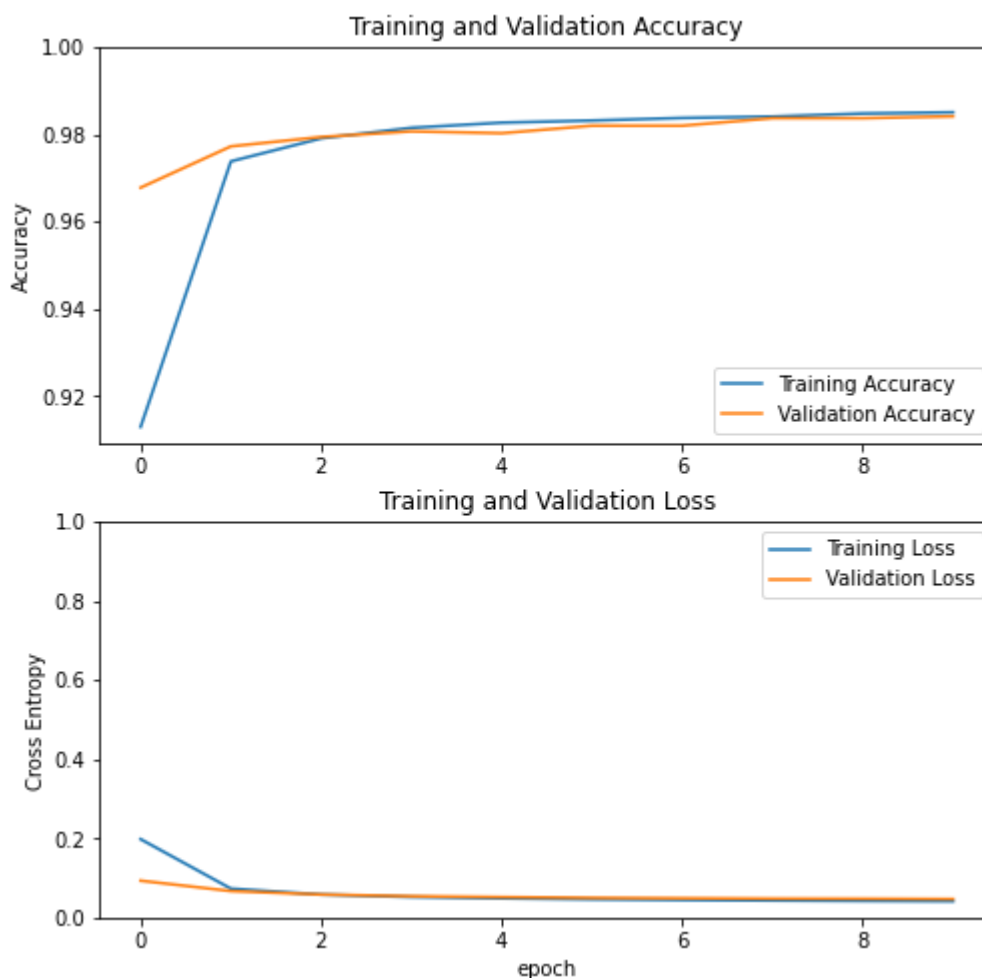

Let's take a look at the learning curves of the training and validation accuracy/loss when using the M extractor.

```
acc = history.history['accuracy']
val_acc = history.history['val_accuracy']
```

```
loss = history.history['loss']
val_loss = history.history['val_loss']

plt.figure(figsize=(8, 8))
plt.subplot(2, 1, 1)
plt.plot(acc, label='Training Accuracy')
plt.plot(val_acc, label='Validation Accuracy')
plt.legend(loc='lower right')
plt.ylabel('Accuracy')
plt.ylim([min(plt.ylim()),1])
plt.title('Training and Validation Accuracy')

plt.subplot(2, 1, 2)
plt.plot(loss, label='Training Loss')
plt.plot(val_loss, label='Validation Loss')
plt.legend(loc='upper right')
plt.ylabel('Cross Entropy')
plt.ylim([0,1.0])
plt.title('Training and Validation Loss')
plt.xlabel('epoch')
plt.show()
```

Note: If you are wondering why the validation metrics are clearly better than the training metrics, the `tf.keras.layers.BatchNormalization` and `tf.keras.layers.Dropout` affect accuracy during training validation loss.

To a lesser extent, it is also because training metrics report the average for an epoch, while validation validation metrics see a model that has trained slightly longer.

▼ Fine tuning

In the feature extraction experiment, you were only training a few layers on top of an MobileNet V2 base network were **not** updated during training.

One way to increase performance even further is to train (or "fine-tune") the weights of the top layers training of the classifier you added. The training process will force the weights to be tuned from general specifically with the dataset.

Note: This should only be attempted after you have trained the top-level classifier with the pre-trained randomly initialized classifier on top of a pre-trained model and attempt to train all layers jointly, the rate too large (due to the random weights from the classifier) and your pre-trained model will forget what

Also, you should try to fine-tune a small number of top layers rather than the whole MobileNet model. higher up a layer is, the more specialized it is. The first few layers learn very simple and generic features images. As you go higher up, the features are increasingly more specific to the dataset on which the model is to adapt these specialized features to work with the new dataset, rather than overwrite the generic

▼ Un-freeze the top layers of the model

All you need to do is unfreeze the `base_model` and set the bottom layers to be un-trainable. Then, you for these changes to take effect), and resume training.

```
base_model.trainable = True

# Let's take a look to see how many layers are in the base model
print("Number of layers in the base model: ", len(base_model.layers))

# Fine-tune from this layer onwards
fine_tune_at = 100

# Freeze all the layers before the `fine_tune_at` layer
for layer in base_model.layers[:fine_tune_at]:
    layer.trainable = False
```

▼ Compile the model

Compile the model using a much lower learning rate.

```
model.compile(loss=tf.keras.losses.BinaryCrossentropy(from_logits=True),
              optimizer = tf.keras.optimizers.RMSprop(lr=base_learning_rate/10),
              metrics=['accuracy'])
```

```
model.summary()
```

Epoch 19/20
582/582 [=====] - 51s 88ms/step - loss: 0.0098 - accuracy: 0.99
Epoch 20/20
582/582 [=====] - 52s 89ms/step - loss: 0.0089 - accuracy: 0.99

```

Let's take a look at the learning curves of the training and validation accuracy/loss when fine-tuning the base model and training the classifier on top of it. The validation loss is much higher than the training loss. You may also get some overfitting as the new training set is relatively small and similar to the original training set.

After fine tuning the model nearly reaches 98% accuracy.

```

acc2 =acc+ history_fine.history['accuracy']
val_acc2 =val_acc+ history_fine.history['val_accuracy']

loss2 =loss+ history_fine.history['loss']
val_loss2=val_loss+ history_fine.history['val_loss']

```

```

plt.figure(figsize=(8, 8))
plt.subplot(2, 1, 1)
plt.plot(acc2, label='Training Accuracy')
plt.plot(val_acc2, label='Validation Accuracy')
plt.ylim([0.8, 1])
plt.plot([initial_epochs-1,initial_epochs-1],
         plt.ylim(), label='Start Fine Tuning')
plt.legend(loc='lower right')
plt.title('Training and Validation Accuracy')

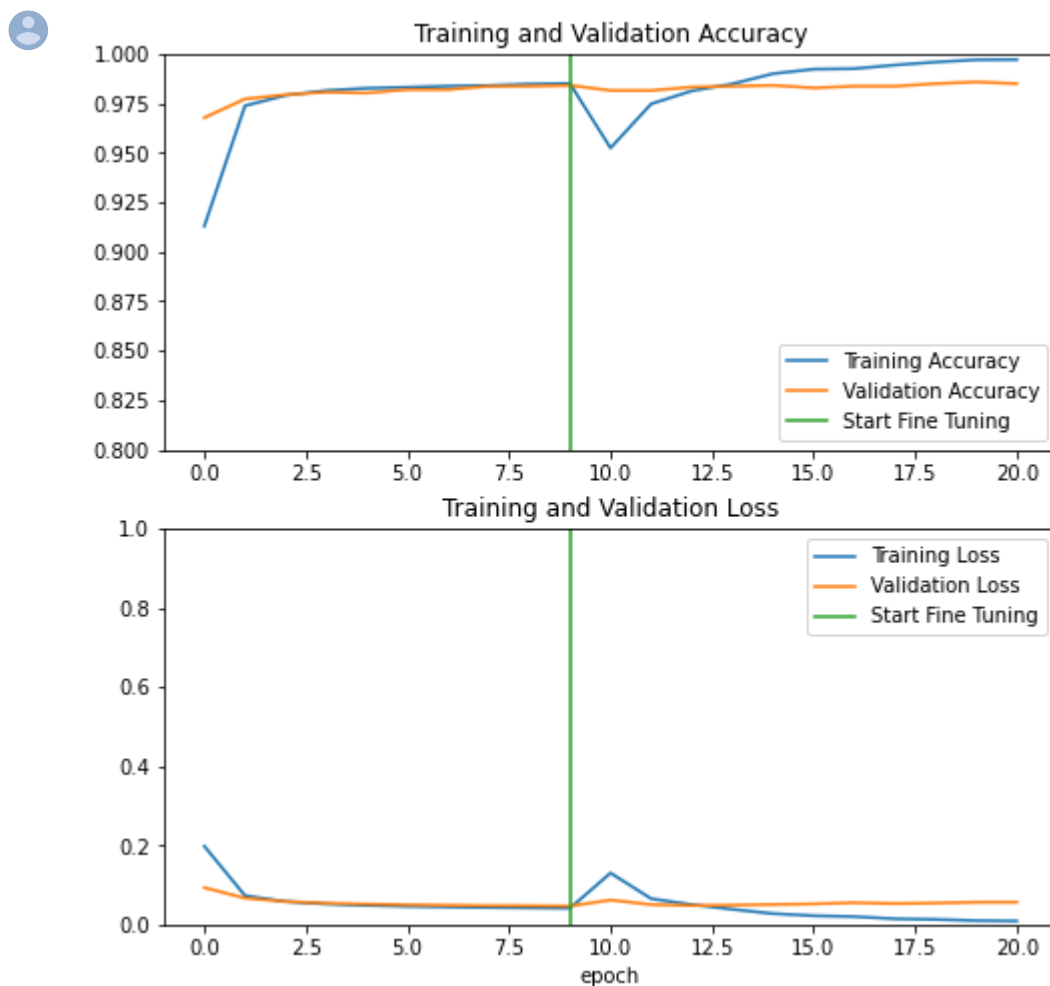

```

```

plt.subplot(2, 1, 2)
plt.plot(loss2, label='Training Loss')
plt.plot(val_loss2, label='Validation Loss')
plt.ylim([0, 1.0])
plt.plot([initial_epochs-1,initial_epochs-1],

```

```
plt.plot([initial_epochs-1, initial_epochs-1],
         plt.ylim(), label='Start Fine Tuning')
plt.legend(loc='upper right')
plt.title('Training and Validation Loss')
plt.xlabel('epoch')
plt.show()
```

▼ Fine tune : 120

```
# Let's take a look to see how many layers are in the base model
print("Number of layers in the base model: ", len(base_model.layers))
